[sklearn.neighbors](#).KNeighborsClassifier

class sklearn.neighbors.KNeighborsClassifier(*n_neighbors=5, *, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None*)   [source]

Classifier implementing the k-nearest neighbors vote.

Read more in the [User Guide](#).

Parameters:

n_neighbors : *int, default=5*
Number of neighbors to use by default for `kneighbors` queries.

weights : *{'uniform', 'distance'} or callable, default='uniform'*
Weight function used in prediction. Possible values:

- 'uniform' : uniform weights. All points in each neighborhood are weighted equally.
- 'distance' : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

algorithm : *{'auto', 'ball_tree', 'kd_tree', 'brute'}, default='auto'*
Algorithm used to compute the nearest neighbors:

- 'ball_tree' will use `BallTree`
- 'kd_tree' will use `KDTree`
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to `fit` method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size : *int, default=30*
Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p : *int, default=2*
Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric : *str or callable, default='minkowski'*
The distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. For a list of available metrics, see the documentation of `DistanceMetric`. If metric is "precomputed", X is assumed to be a distance matrix and must be square during fit. X may be a [sparse graph](#), in which case only "nonzero" elements may be considered neighbors.

metric_params : *dict, default=None*
Additional keyword arguments for the metric function.

n_jobs : *int, default=None*
The number of parallel jobs to run for neighbors search. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See [Glossary](#) for more details. Doesn't affect `fit` method.

Toggle Menu

classes_ : *array of shape (n_classes,)*
    Class labels known to the classifier

effective_metric_ : *str or callble*
    The distance metric used. It will be same as the `metric` parameter or a synonym of it, e.g. 'euclidean' if the `metric` parameter set to 'minkowski' and `p` parameter set to 2.

effective_metric_params_ : *dict*
    Additional keyword arguments for the metric function. For most metrics will be same with `metric_params` parameter, but may also contain the `p` parameter value if the `effective_metric_` attribute is set to 'minkowski'.

n_features_in_ : *int*
    Number of features seen during [fit](#).

    New in version 0.24.

feature_names_in_ : *ndarray of shape (`n_features_in_`,)*
   Names of features seen during [fit](#). Defined only when `X` has feature names that are all strings.

    New in version 1.0.

n_samples_fit_ : *int*
    Number of samples in the fitted data.

outputs_2d_ : *bool*
    False when `y`'s shape is (n_samples,) or (n_samples, 1) during fit otherwise True.

Notes

See [Nearest Neighbors](#) in the online documentation for a discussion of the choice of `algorithm` and `leaf_size`.

> **Warning:** Regarding the Nearest Neighbors algorithms, if it is found that two neighbors, neighbor `k+1` and `k`, have identical distances but different labels, the results will depend on the ordering of the training data.

Examples

Toggle Menu

```
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import KNeighborsClassifier
>>> neigh = KNeighborsClassifier(n_neighbors=3)
>>> neigh.fit(X, y)
KNeighborsClassifier(...)
>>> print(neigh.predict([[1.1]]))
[0]
>>> print(neigh.predict_proba([[0.9]]))
[[0.666... 0.333...]]
```

Methods

fit(X, y)	Fit the k-nearest neighbors classifier from the training dataset.
get_params([deep])	Get parameters for this estimator.
kneighbors([X, n_neighbors, return_distance])	Find the K-neighbors of a point.
kneighbors_graph([X, n_neighbors, mode])	Compute the (weighted) graph of k-Neighbors for points in X.
predict(X)	Predict the class labels for the provided data.
predict_proba(X)	Return probability estimates for the test data X.
score(X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

---

fit(*X*, *y*) [source]

Fit the k-nearest neighbors classifier from the training dataset.

Parameters:

X : {array-like, sparse matrix} of shape (n_samples, n_features) or (n_samples, n_samples) if metric='precomputed'
Training data.

y : {array-like, sparse matrix} of shape (n_samples,) or (n_samples, n_outputs)
Target values.

Returns:

self : KNeighborsClassifier
The fitted k-nearest neighbors classifier.

---

get_params(*deep=True*) [source]

Get parameters for this estimator.

Parameters:

deep : bool, default=True
If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns:

params : dict
Parameter names mapped to their values.

---

kneighbors(*X=None, n_neighbors=None, return_distance=True*) [source]

Toggle Menu   eighbors of a point.

Returns indices of and distances to the neighbors of each point.

Parameters:

X : array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'precomputed', default=None
The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors : int, default=None
Number of neighbors required for each sample. The default is the value passed to the constructor.

return_distance : bool, default=True
Whether or not to return the distances.

Returns:

neigh_dist : ndarray of shape (n_queries, n_neighbors)
Array representing the lengths to points, only present if return_distance=True.

neigh_ind : ndarray of shape (n_queries, n_neighbors)
Indices of the nearest points in the population matrix.

◄   ►

Examples

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who's the closest point to [1,1,1]

```
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]]...)
```

---

kneighbors_graph(*X=None, n_neighbors=None, mode='connectivity'*)   [source]

Compute the (weighted) graph of k-Neighbors for points in X.

Parameters:

X : array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'precomputed', default=None
The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor. For `metric='precomputed'` the shape should be (n_queries, n_indexed). Otherwise the shape should be (n_queries, n_features).

n_neighbors : int, default=None
Number of neighbors for each sample. The default is the value passed to the constructor.

mode : {'connectivity', 'distance'}, default='connectivity'
Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are distances between points, type of distance depends on the selected metric parameter in NearestNeighbors class.

Toggle Menu

Returns:

A : *sparse-matrix of shape (n_queries, n_samples_fit)*
`n_samples_fit` is the number of samples in the fitted data. `A[i, j]` gives the weight of the edge connecting `i` to `j`. The matrix is of CSR format.

◄   ▸

Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])
```

---

predict(*X*)   [source]

Predict the class labels for the provided data.

Parameters:

X : *array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'precomputed'*
Test samples.

Returns:

y : *ndarray of shape (n_queries,) or (n_queries, n_outputs)*
Class labels for each data sample.

◄   ▸

---

predict_proba(*X*)   [source]

Return probability estimates for the test data X.

Parameters:

X : *array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'precomputed'*
Test samples.

Returns:

p : *ndarray of shape (n_queries, n_classes), or a list of n_outputs of such arrays if n_outputs > 1.*
The class probabilities of the input samples. Classes are ordered by lexicographic order.

◄   ▸

---

score(*X, y, sample_weight=None*)   [source]

Return the mean accuracy on the given test data and labels.

Toggle Menu

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters:

X : *array-like of shape (n_samples, n_features)*
    Test samples.

y : *array-like of shape (n_samples,) or (n_samples, n_outputs)*
    True labels for `X`.

sample_weight : *array-like of shape (n_samples,), default=None*
    Sample weights.

Returns:

score : *float*

   Mean accuracy of `self.predict(X)` wrt. `y`.

---

set_params(**params*)   [source]

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.
**Parameters:**

**params : *dict*
    Estimator parameters.

Returns:

self : *estimator instance*
    Estimator instance.
